INSTACART GROCERY BASKET ANALYSIS

Instacart's 3M kitchen, customer base was analysed utilising **Python** in **Jupyter Notebook** with libraries – **Pandas, Numpy, Scipy, Matplotlib,seaborn** and **Sedacorn** – to assess key purchasing behaviors.

This case study details the analytical process undertaken and the skills developed throughout. For immediate access to the findings and visuals, please click the link below:

REPORT | GITHUB

BACKGROUND

Instacart wants a deeper understanding of their customers and their purchasing behavior. They are interested in creating customer profiles to target their marketing campaigns and measure how these strategies affect proceeding sales.

NEED

Perform an initial exploratory analysis about their customers and their purchasing behaviors. Then create customer profiles and suggest marketing strategies for each group.

QUESTIONS ADDRESSED:

What days and times are the busiest / are customers spending the most?

What are the usage profiles of the products by segments?

What types of products are more popular than others?

Which departments have the highest frequency of orders?

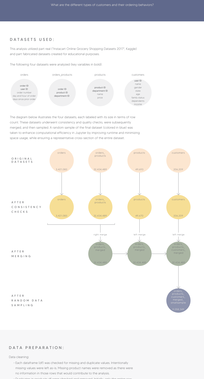
What are the different types of customers and their ordering behaviors?

DATASETS USED:

The analysis utilised real data* from Instacart Online Grocery Shopping Dataset 2017, Kaggle and part-fabricated datasets created for educational purposes.

The following four datasets were analysed (key variables in bold):

The diagram below illustrates the four datasets, each labelled with its size in terms of row count. These datasets underwent consistency and quality checks, were subsequently merged, and then underwent a random data sample to create a smaller dataset for ease of use. Lastly, customer behavioural attributes were engineered to create key features and ordering profiles.



DATA PREPARATION:

Data cleaning:

Each dataframe QA was checked for missing and duplicate values. Importantly, missing values were dealt with as it's fitting product names were removed or there was no information in those rows that would contribute to the analysis.

Duplicate values were found in the orders dataframe, where all the entire row duplicates were removed. Accidental and orders 48 were retained as these were likely other individual product, as duplicates counting as customer of 13% duplicates prior removal. These product_id duplicates were removed from products df, then merged again, resulting in a clean merge.

Consistency checks on the remaining process yielded no issues.

Data wrangling:

Orders data were reviewed and standardised across df's. Index numbers or numbers that did not require calculation were changed from integer to string/object to when running the descriptive analytics, they were not calculated.

New df subsets were created, extracting only the relevant columns.

Data was then merged into one large dataframe.

Merge checked with assert argument to ensure merge was successful.

Data transformation:

The four df's were merged prior to the user_id level data diagram, given the total. If statements were used to create subcolumn of certain customers, as well as creating conditional columns, from which customer profiles were created (see subsets below to see full scripts).

A random sample of the df was taken to reduce the size to 10%.

Excluding low activity customers

```
# Remove low spending customers from dataset

low_activity = ords_prods_cust_merge[(ords_prods_cust_merge['prices'] < 3) & (ords_prods_cust_merge['order_number'] < 5)]

low_activity.shape

(1440307, 34)

ords_prods_cust_merge = ords_prods_cust_merge[~((ords_prods_cust_merge['prices'] < 3) & (ords_prods_cust_merge['order_number'] < 5))]

ords_prods_cust_merge.shape

(32434489, 34)
```

Random data sample

```
# Create a sample containing 10% of the rows in the original dataset

sample = np.random.rand(len(ords_prods_cust_merge)) <= 0.1

sample

array([False, False, False, ..., False, False, False])

len(sample)

32434489

# Store sample as a separate dataframe

df_sample = ords_prods_cust_merge[sample]

df_sample.shape

(3243448, 34)
```

Customer Profiles Yearly Structure

```
# Create a new column 'spending_flag'

ords_prods_cust_merge.loc[ords_prods_cust_merge['prices'] < 100, 'spending_flag'] = 'Mid range product'

ords_prods_cust_merge.loc[ords_prods_cust_merge['prices'] >= 100, 'spending_flag'] = 'High range product'

ords_prods_cust_merge['spending_flag'].value_counts(dropna = False)

Mid range product    30964564
High range product     1469925
Name: spending_flag, dtype: int64

# Create a new column 'order_frequency_flag'

ords_prods_cust_merge.loc[ords_prods_cust_merge['days_since_prior_order'] <= 10, 'order_frequency_flag'] = 'Frequent customer'

ords_prods_cust_merge.loc[(ords_prods_cust_merge['days_since_prior_order'] > 10) & (ords_prods_cust_merge['days_since_prior_order'] <= 20), 'order_frequency_flag'] = 'Regular customer'

ords_prods_cust_merge.loc[ords_prods_cust_merge['days_since_prior_order'] > 20, 'order_frequency_flag'] = 'Non-frequent customer'

ords_prods_cust_merge['order_frequency_flag'].value_counts(dropna = False)

Regular customer        15347662
Frequent customer       10978964
Non-frequent customer    6107863
Name: order_frequency_flag, dtype: int64
```

Customer Profile Age & Income

```
# Create a new column 'age_group'

ords_prods_cust_merge.loc[ords_prods_cust_merge['age'] <= 34, 'age_group'] = 'Young adult'

ords_prods_cust_merge.loc[(ords_prods_cust_merge['age'] > 34) & (ords_prods_cust_merge['age'] <= 54), 'age_group'] = 'Middle age'

ords_prods_cust_merge.loc[ords_prods_cust_merge['age'] > 54, 'age_group'] = 'Senior'

ords_prods_cust_merge['age_group'].value_counts(dropna = False)

Middle age    10809578
Senior        10808284
Young adult   10816627
Name: age_group, dtype: int64

# Create a new column 'income_group'

ords_prods_cust_merge.loc[ords_prods_cust_merge['income'] <= 100000, 'income_group'] = 'Low income'

ords_prods_cust_merge.loc[(ords_prods_cust_merge['income'] > 100000) & (ords_prods_cust_merge['income'] <= 200000), 'income_group'] = 'Middle income'

ords_prods_cust_merge.loc[ords_prods_cust_merge['income'] > 200000, 'income_group'] = 'High income'

ords_prods_cust_merge['income_group'].value_counts(dropna = False)

Middle income    21622284
Low income       10812205
High income          8000
Name: income_group, dtype: int64
```

DATA EXPLORATION:

After the creation of the conditional columns, descriptive analysis and visualisations were generated to gain further insights.

Below are the conditional columns and customer profiles created, as well as an example of a descriptive analysis (click image to see entire script):

CONDITIONAL COLUMNS

CUSTOMER PROFILES

Descriptive analysis of family structure

```
# Select relevant columns

df_family = ords_prods_cust_merge[['number_of_dependants', 'marital_status', 'age', 'income']]

# Descriptive statistics

df_family.describe()

       number_of_dependants           age         income
count          3.243449e+07  3.243449e+07   3.243449e+07
mean           1.499999e+00  4.946000e+01   9.967000e+04

25%            0.000000e+00  3.300000e+01   6.667000e+04
50%            1.000000e+00  4.900000e+01   9.661000e+04
75%            3.000000e+00  6.500000e+01   1.329000e+05
max            3.000000e+00  8.100000e+01   5.939010e+05

# Crosstab

df_family.groupby('marital_status').agg({'number_of_dependants': ['mean', 'min', 'max']})

                number_of_dependants
                                mean min max
marital_status
divorced/widow                  1.5   0   3
living with parents and siblings  1.5   0   3
married                         1.5   0   3
single                          1.5   0   3
```

Clones

1. completely self-dependents
   - 0% DEP
   - single, divorced/widow
2. homes with dependents
   - 100% DEP
   - married, living with parents and siblings

* These clones were created to present grouping that emerged after exploring the dataframes. Here, the descriptive analysis of family structure

Clones

1. completely self-dependents
   - 0% DEP
   - age: 18-81 (orginal)
   - income: 25,901 - 593,901 (orginal)
2. higher income, 100,000+
   - higher income: 200,000-593,901
   - age: 18-81 (orginal)
3. middle income, 40,000-100,000
   - not include: 200,000-593,901
   - higher income: 200,000-593,901

* These clones were created to present grouping that emerged after income was distributed in scatterplots

CHALLENGES:

Data Wrangling:

The customer behavior fabricated for educational purposes included attributes such as income, which was not realistic in relation to the number of orders.

Distribution of the number of dependants and age (18-81) was also not realistic, with uniform, obscuring insights. Clones.

There were nearly uniform spending habits per each age, resulting in 3 customer profiles based on age groups (18-34 young adult, 35-54 middle age, 55-81 senior) – these were subsequently grouped into 'completely dependents' and 'non-dependents'.

The method employed needed integration of the different user groups might be engaging with Instacart. It reflected a combination of order volumes and age, rather than these being due to a differentiated lifestyle.

Python visualisation:

Some of the visualisations faced when creating stacked bar charts with Python (seaborn and matplotlib) due to its limitations with the null and plotly Python's extensive in the ability to customise colors and text for values and examples.

- A workaround could have been to export the data to Tableau, or import .png of the visuals into Adobe Illustrator for customisation. While the visuals created were not perfect, they were sufficient for exploratory analysis, and the time saved was worthwhile for this assessment.

Skill Gaps:

There were moments where ERP usage was reaching maximum capacity, resulting in long run times, particularly when creating some more complex visuals.

- To reduce the size of the df, a random sample was created.
- In hindsight, the df size could have reduced by removing irrelevant columns earlier in the process, such as first_name, last_name, and gender. Not redundant. By disabling between data, it may have been possible to see the errors of instead of a sample.

Hindsight, Organisation:

- In a single notebook, the data aggregation, interrogation, and the full analysis was incorporated.
- The notebook was later organised with markdown titles, subsections, and comments. However, navigating the notebook remained somewhat difficult. Scripts and results quickly accrued.
- This would have benefited from having two notebooks: one for data preparation and another for the exploratory analysis and visualisations. Unfortunately, I realised this at the point that the second file started with the same df and any adjustments to the df made in the first notebook, and the revised data re-implemented into all on the second notebook to complete the analysis.

REPORT HIGHLIGHTS:

Regular customers order 20% of orders
Mid range and High range products
Mid range spend 10% more than high range
Mid range
High range
Regular customers
Frequent customers
Non-frequent customers
Most loyal customers
Most popular products
Most popular products
Most popular products
